ChatScript System Variables and Engine-defined Concepts

- Engine-defined Concepts
- System Variables
- Control over Input
- Interchange Variables

Engine-defined concepts

In addition to concepts defined in script files, the system automatically defines a bunch of dictionary-based sets as well as dynamically computed concept members.

Interjections, "discourse acts", and concept sets

Some words and phrases have interpretations based on whether they are at sentence start or not. E.g., good day, mate and It is a good day are different for good day.

Likewise sure and I am sure are different. Words that have a different meaning at the start of a sentence are commonly called interjections.

In ChatScript these are defined by the livedata/interjections.txt file. In addition, the file augments this concept with "discourse acts", phrases that are like an interjection. All interjections and discourse acts map to concept sets, which come thru as the user input instead of what they wrote. For example yes and sure and of course are all treated as meaning the discourse act of agreement in the interjections file. So you don't see yes, I will go coming out of the engine.

The interjections file will remap that to the sentence ~yes, breaking off that into its own sentence, followed by I will go as a new sentence.

These generic interjections (which are open to author control via interjections.txt) are: * ~yes * ~no * ~emomaybe * ~emohello * ~emogoodbye * ~emohowzit * ~emothanks * ~emolaugh * ~emohappy * ~emosad * ~emosurprise * ~emomisunderstand * ~emoskeptic * ~emoignorance * ~emobeg * ~emobored * ~emopain * ~emoangry * ~emocurse * ~emodisgust * ~emoprotest * ~emoapology * ~emomutual

Because all interjections at the start of a sentence are broken off into their own sentence, this kind of pattern does not work:

u: (~yes _*)

You cannot capture the rest of the sentence here, because it will be part of the next sentence instead. This means interjections act somewhat differently from other concepts.

If you use a word in a pattern which may get remapped on input, the script compiler will issue a warning. Likely you should use the remapped name instead.

The following concepts are triggered by exactly repeating either the chatbot or oneself (to a repeat count of how often repeated). Repeats are within a recency

```
window of about 20 volleys. * ~repeatme * ~repeatinput1 * ~repeatinput2 * ~repeatinput3 * ~repeatinput4 * ~repeatinput5 * ~repeatinput6
```

POS (Part of Speech) Tags

Words will have pos-tags attached, specififying both generic and specific tag attributes, eg., * ~noun * ~noun_singular.

Generic Specifics

- ~noun
- ~noun singular
- ~noun_plural
- ~noun_proper_singular
- ~noun_proper_plural
- ~noun_gerund
- ~noun_number
- ~noun infinitive
- ~noun_omitted_adjective
- ~verb
- ~verb_present
- ~verb_present_3ps
- ~verb_infinitive
- ~verb_present_participle
- ~verb_past
- ~verb_past_participle
- ~aux_verb
- ~aux_verb_present
- ~aux_verb_past
- ~aux_verb_future
- ~aux_verb_tenses
- ~aux_be
- ~aux_have
- ~aux_do

Auxilliary verbs are segmented into normal ones and special ones. Normal ones give their tense directly. Special ones give their root word. The tense of the be/have/do verbs can be had via 'properties() and testing for verb tenses

- ~adjective
- ~adjective_normal
- ~adjective_number
- ~adjective_noun
- ~adjective_participle

Adjectives in comparative form will also have * ~more_form or ~most_form. * ~adverb * ~adverb_normal

Adverbs in comparative form will also have * ~more_form or ~most_form * ~pronoun, ~pronoun_subject, ~pronoun_object * ~conjunction_bits, ~conjunction_coordinate, ~conjunction_subordinate * ~determiner_bits, ~determiner, ~pronoun_possessive, ~predeterminer * ~possessive (covers ' and 's at end of word) * ~to_infinitive ("to" when used before a noun infinitive) * ~preposition, ~particle (free-floating preposition tied to idiomatic verb) * ~comma * ~quote (covers ' and _ "_ when not embedded in a word) * ~paren (covers opening and closing parens) * ~foreign_word (some unknown word) * ~there_existential (the word there used existentially)

In addition to normal generic kinds of postags, words which are serving a postag role different from their putative word type are marked as members of the major tag they act as part of. E.g.,

- ~noun gerund verb used as a ~noun
- ~noun_infinitive verb used as a ~noun
- ~noun_omitted_adjective an adjective used as a collective noun (eg the beautiful are kind)
- ~adjectival_noun (noun used as adjective like bank "bank teller")
- ~adjective_participle (verb participle used as an adjective)

For ~noun_gerund in *I like swimming* the verb gerund *swimming* is treated as a noun (hence called noun-gerund) but retains verb sense when matching keywords tagged with part-of-speech (i.e., it would match swim~v as well as swim~n).

- ~number is not a part of speech, but is comprise of ~noun_number (a normal number value like 17 or seventeen)
- ~adjective_number (also a normal numeral value and also ~placenumber) like first.

Additionally, there is * ~integer * ~float * ~positiveinteger * ~negativeinteger * ~modelnumber (not a true number, but a word with both alpha and numeric)

To can be a preposition or it can be special. When used in the infinitive phrase To go, it is marked ~to_infinitive and is followed by ~noun_infinitive.

- ~verb_infinitive refers to a match on the infinitive form of the verb (*I hear John sing* or *I will sing*).
- ~There_existential refers to the use of where not involving location, meaning the existence of, as in There is no future.
- ~Particle refers to a preposition piece of a compound verb idiom which allows being separated from the verb. If you say *I will call off the meeting*, call_off is the composite verb and is a single token. But if you split it as in *I will call the meeting off*, then there are two tokens. The original form

of the verb will be call and the canonical form of the verb will be call_off, while the free-standing off will be labeled ~particle.

- ~verb_present will be used for normal present verbs not in third person singular like *I walk* and
- ~verb_present_3ps will be used for things like he walks
- ~possesive refers to 's and ' that indicate possession, while possessive pronouns get their own labeling ~pronoun_possessive.
- ~pronoun_subject is a pronoun used as a subject (like he) while
- ~pronoun_object refers to objective form like him

Individual words serve roles in the parse of a sentence, which are retrievable. These include:

- ~mainsubject
- ~mainverb
- ~mainindirect
- ~maindirect
- ~subject2
- ~verb2
- ~indirectobject2
- ~object2
- ~subject_complement (adjective object of sentence involving linking verb).
- ~object_complement (2ndary noun or infinitive verb filling modifying mainobject or object2),
- ~conjunct_noun, ~conjunct_verb, ~conjunct_adjective, ~conjunct_adverb
- ~conjunct_phrase, ~conjunct_clause, ~conjunct_sentence
- ~postnominalAdjective adjective occuring AFTER the noun it modified
- ~reflexive (reflexive pronouns)
- ~not
- ~address noun used as addressee of sentence
- ~appositive noun restating and modifying prior noun
- ~absolutephrase special phrase describing whole sentence
- \sim omittedtimeprep modified time word used as phrase but lacking preposition (Next tuesday I will go)
- ~phrase a prepositional phrase start (except
- ~clause a subordinate clause start |
- ~verbal a verb phrase |

System Variables

The system has some predefined variables which you can generally test and use but not normally assign to. These all begin with %. Ones that are reasonable to set are written in bold underline. Boolean values are always 1 or null on returns. 1 or 0 if you are setting them.

Date & Time & Numbers

variable description %date one or two digit day of the month %day Sunday, etc %daynumber0-6 where 0 = Sunday %fulltime seconds representing the current time and date		
%day Sunday, etc %daynumber 0-6 where 0 = Sunday %fulltime seconds representing the current time and date	variable	description

Build data+

variable	description
%dict	date/time the dictionary was built
%engine	date/time the engine was compiled
%os	os invovled (linux windows mac ios)
%script	date/time build1 was compiled
%version	engine version number

You actually can assign to any of them. This will override them and make them return what you tell them to and is a particularly BAD thing to do if this is running on a server since it affects all users (unless you reset the variable at the

end of the volley. Assigning a period to a variable resets it). Typically one does this as a temporary assignment in a #! comment line to set up conditions for testing using :verify. Making them return a new value is NOT the same thing as making the engine have a different value. Unless the variable is marked as settable, setting a value affects only the value returned by a future call to the system variable. It does not change engine values the variable is meant to reflect.

Control Over Input

The system can do a number of standard processing on user input, including spell correction, proper-name merging, expanding contractions etc. This is managed by setting the user variable \$cs token.

The default one that comes with Harry is:

```
$cs_token = #D0_INTERJECTION_SPLITTING |
    #D0_SUBSTITUTE_SYSTEM |
    #D0_NUMBER_MERGE |
    #D0_PROPERNAME_MERGE |
    #D0_SPELLCHECK |
    #D0_PARSE
```

The #signals a named constant from the dictionarySystem.h file. One can set the following:

These enable various LIVEDATA files to perform substitutions on input:

```

The contents of the files are pairs of tokens per line. Left is the word to replace and right is the replacement. When multiple words are involved, the left side uses underscores to represent this and the right side uses +. If the right side is missing, it means just delete.

If any of the above items affect the input, they will be echoed as values into %tokenFlags so you can detect they happened. The next changes do not echo into %tokenFlags and relate to grammar of input:

flag description
```

Note, you can change \$cs_token on the fly and force input to be reanalyzed via ^retry(SENTENCE). I do this when I detect the user is trying to give his name, and many foreign names might be spell-corrected into something wrong and the user is unlikely to misspell his own name. Just remember to reset \$cs_token back to normal after you are done. Here is one such way, assuming \$stdtoken is set to your normal tokenflags in your bot definition outputmacro:

If you type my name is Rogr into a topic with this, the original input is spell-corrected to my name is Roger, but this will change the \$cs_token over to one without spell correction and redo the sentence, which will now come back with my name is Rogr and be echoed correctly, and \$cs_token reset. That's assuming nothing else would run differently and trap the response elsewhere. If you were worried about that, it would be possible for the script to save where it is using `getrule(tag) and modify your control script to return immediate control to here after input processing if you had changed \$cs_token.

Private Substitutions

While in general, substitutions are defined in the LIVEDATA folder, you can define private substitutions for your specific bot using the scripting language. You can say

```
replace: xxx yyyyy
```

which defines a substitution just like a livedata substitution file. It actually creates a substitution file called privateO.txt or private1.txt in your TOPIC folder. Even then, those substitutions will not be enacted unless you explicitly add to the \$cs_token value #DO_PRIVATE, eg

```
#DO_NUMBER_MERGE |
#DO_PROPERNAME_MERGE |
#DO_SPELLCHECK |
#DO_PARSE |
#DO_PRIVATE
```

The left side of the substitution pair is case insensitive (matches either case on input) and can be placed in double-quotes (which converts spaces to underscorers).

Similarly while canonical values of words can be defined in LIVEDATA/SYSTEM/canonical.txt, you can define private canonical values for your bots by using the scripting language. You can say:

```
canon: oh 0 faster fast
```

which defines new canonical values for things and creates a file canon0.txt or canon1.txt in your TOPIC folder. If you want to set a canonical pair from a table during compilation, you can use a function to do the same thing (but only 1 pair at a time).

Interchange Variables

The following variables can be defined in a script and the engine will react to their contents.

interchange variable	description
\$cs_token	described
	exten-
	sively
	above

[^]canon(word canonicalform)

```
interchange variable
                      {\it description}
                      controls
$cs_response
                      auto-
                      matic
                      han-
                      dling of
                      outputs
                      to user.
                      By
                      default
                      it
                      consists
                      of
                      $cs_response
                      #Response_upperstart
                      #response_removespacebeforecomma
                      #response_alterunderscores
                      #response_removetilde
                      If you
                      want
                      none of
                      theses,
                      use
                      cs_response
                      =0 (all
                      flags
                      turned
                      off).
                      See
                      ^print
                      for
                      expla-
                      nation
                      of flags.
                      #response_noconvertspecial
                      - leave
                      escaped
                      n r and
                      t alone
                      in
                      output
                      and
                      \log
             31
                      #response_upperstart
                      - makes
                      the first
                      letter of
                      an
                      output
                      sen-
                      tence
```

interchange variable description $cs_{\without model} \$ matchvariable covers multiple words, what should separatethemby default it's a space, but underscore is handy too. Initial system character is space, creating ${\it fidelity}$ with what was typed. Useful if $_$ can be recognized in input (web addresses). Changing to _ is consistent with multi-41 word representation

and keyword recogni-
